1. Introduction

ADMS models three plume depletion processes: dry deposition, wet deposition and radioactive decay. This paper describes the radioactive decay module. All three processes lead to a variation with downwind distance, or travel time, of the plume strength Q :

$$Q(x) = \int_{-\infty}^{\infty} dy \int_0^{\infty} C(x, y, z) U dz \quad (1)$$

where U is the mean wind speed and C is the concentration.

It is assumed that:

- (i) Removal processes act independently;
- (ii) Removal processes are irreversible

The first assumption implies that plume strength can be written as a product of source strength and depletion factors corresponding to each removal process. Where species with significantly different deposition parameters are present in the release a separate calculation must be performed for each. Variation of deposition parameters with the formation of new isotopes following radioactive decay cannot, however, be modelled and the values of dry deposition velocity and washout coefficient specified by the user should reflect the contents of the initial isotope inventory. Deposition of daughter isotopes could alternatively be estimated by post-processing the model output using the expression $D(x, y) = v_d C(x, y, z = 0)$, where D is the deposition flux and v_d the dry deposition velocity, see technical specification P17/13 for more details.

Removal processes are integrated into the dispersion model as follows. Let $C_1(x, y, z)$ be the mean activity *per unit source strength* in the absence of deposition or radioactive decay. The activity of the i th isotope in the inventory, $C_i(x, y, z)$, is then given by

$$C_i(x, y, z) = Q_i C_1(x, y, z) \quad (2)$$

The amount of each radioisotope is given as a fraction of the total mass release. Thus, if q_i is the amount of isotope i in the release in mol kg⁻¹ and Q the total activity, the total plume strength for isotope i is:

$$Q_i = q_i Q \quad (3)$$

The variation of q_i with travel time is computed by the Radioactive Decay Module, which is described in the next section.

2. Modelling Radioactive Decay

Radioactive decay is calculated for a set of isotopes given their parent isotopes and decay constants (or half-lives). The main parameters used are given in Table 1.

Process	Parameters
Radioactive decay	$\{\lambda_i\}$ - decay constants $\{f_{ij}\}$ - decay fraction $i \rightarrow j$

Table 1: Modelling parameters

The sources of radioactive decay data are described in paper P17/06.

The Radioactive Decay Module solves the coupled ordinary differential equations governing the transformation of radioactive isotopes [1]:

$$\frac{dq_i}{dt} = -\lambda_i q_i + \sum_{j \neq i} f_{ji} \lambda_j q_j \quad (4)$$

where:

q_i = number fraction (mol kg^{-1}) of isotope i in the emission;

λ_i = decay constant of isotope i ;

f_{ji} = fraction of isotope j decaying into i .

For plumes i.e. continuous releases, the “age” of the material at a downstream position x , is given by:

$$t = \int_0^x \frac{dx}{U(z_m)} \quad (5)$$

where z_m is the mean plume height.

The decay constant λ_i is related to the half-life $T_{1/2}$ by:

$$T_{1/2} = \frac{\ln 2}{\lambda} \quad (6)$$

and the number fraction is related to the activity A in Bequerels per kg (Bq kg^{-1}) of that isotope by:

$$A_i = \lambda_i q_i \quad (7)$$

Appendix A gives a list of the isotopes included in ADMS with their halflives and decay products [2].

Calculation of gamma dose is described in ADMS Technical Specification P20/01.

3. Finite Releases

Radioactive decay from finite (puff) releases can be calculated by the model for short term averages as time integrated or time dependent activity output. The coupled ordinary differential equations governing the transformation of radioactive isotopes are solved as for plumes, see §2.

For time dependent puff output, equation (5) which gives the “age” of the material at a downstream position x , is replaced by the expression in equation (8):

$$t = \int_0^x \frac{dx}{U(z_s)} - t_{start} \quad (8)$$

where t_{start} is the start time of the puff and z_s is the original source height. z_s is used in place of z_m as the mean plume height varies at each downstream position with each puff output time and is poorly defined outside the plateau region of the puff.

4. Nomenclature

A_i	isotope activity in Becquerels per kg
f_{ji}	fraction of isotope j decaying into i
Q	plume strength
q_i	number fraction of isotope i in the emission
Q_s	source strength
t	travel time
t_{start}	start time of puff release
$T_{1/2}$	half-life
$U(z)$	wind speed at height z
z_m	mean plume height
z_s	plume height
λ_i	decay constant of isotope i

Subscripts

i	isotope index
s	source
1	per unit plume strength

*This fraction rounds to 1.000 when shown to three decimal places, but is actually less than one.

(P) denotes particulate isotope

† (ME) denotes iodine in the form of methyl iodide
